

## HKPolyUx: ANA101x Human Anatomy

### Module 2 – Human Anatomy >

### Submodule 2.1 - Body Organization and Skeletal System >

### Session 2.1.1 - Organization of human body

Before you begin to study the different structures and functions of the human body, it is helpful to consider its basic architecture; that is, how its smallest parts are assembled into larger structures. It is convenient to consider the structures of the body in terms of fundamental levels of organization that increase in complexity: subatomic particles, atoms, molecules, organelles, cells, tissues, organs, organ systems, organisms and biosphere.

The video player displays a diagram titled "Organization levels of the body" with the video ID HKPANA10T215-V000300. The diagram illustrates the hierarchy of biological organization using the urinary tract system as an example. It is divided into two main sections within a trapezoidal frame:

- Organ level:** Described as "Two or more different tissues combine to form an organ." It features an anatomical illustration of a bladder, with labels for "Bladder", "Skeletal muscle", and "Smooth muscle".
- Organ system level:** Described as "Two or more organs work closely together to perform the functions of a body system." It features an anatomical illustration of the "Urinary tract system", with labels for "Kidney", "Ureter", "Bladder", and "Urethra".

To the right of the main diagram is a smaller pyramid diagram representing the full hierarchy of biological organization, from atoms at the base to the biosphere at the top. The video player interface includes a play button, a progress bar at 0:00 / 1:29, a speed control set to 1.25x, and icons for volume, full screen, closed captions, and a share button.

**The Levels of Organization:** To study the chemical level of organization, scientists consider the simplest building blocks of matter: subatomic particles, atoms and molecules. All matter in the universe is composed of one or more unique pure substances called elements, familiar examples of which are hydrogen, oxygen, carbon, nitrogen, calcium, and iron. The smallest unit of any of these pure substances (elements) is an atom. Atoms are made up of subatomic particles such as the proton, electron and neutron. Two or more atoms combine to form a molecule, such as the water molecules, proteins, and sugars found in living things. Molecules are the chemical building blocks of all body structures.

A cell is the smallest independently functioning unit of a living organism. Even bacteria, which are extremely small, independently-living organisms, have a cellular structure. Each bacterium is a single cell. All living structures of human anatomy contain cells, and almost all functions of human physiology are performed in cells or are initiated by cells.

A human cell typically consists of flexible membranes that enclose cytoplasm, a water-based cellular fluid together with a variety of tiny functioning units called organelles. In humans, as in all organisms, cells perform all functions of life. A tissue is a group of many similar cells (though sometimes composed of a few related types) that work together to perform a specific function. An organ is an anatomically distinct structure of the body composed of two or more tissue types. Each organ performs one or more specific physiological functions. An organ system is a group of organs that work together to perform major functions or meet physiological needs of the body.
